The strong coupling constant $g_{h_b B_c^{PS} B_c^V}$ is calculated using the three-point QCD sum rules method. We use correlation functions to obtain these strong coupling constants with contributions of both B_c^{PS} and B_c^V mesons as off-shell states. The contributions of two gluon condensates as a radiative correction are considered. The results show that $g_{h_b B_c^{PS} B_c^V} = 8.80 \pm 2.84 GeV^{-1}$ and $g_{h_b B_c^V B_c^{PS}} = 9.34 \pm 3.12 GeV^{-1}$ in the B_c^{PS} and B_c^V off-shell state, respectively.

I. INTRODUCTION

Measurements of masses, total widths and transition rates of heavy quark bound states serve as important benchmarks for the predictions of QCD-inspired potential models, non-relativistic QCD, lattice QCD and QCD sum rules[1]. The h_b mesons are bound states of $\bar{b}b$ quarks. The system is approximately non-relativistic due to the large b quark mass, and therefore the quark-antiquark QCD potential can be investigated via $\bar{b}b$ spectroscopy. These mesons are intermediate states between $Y(3S)$ to $\eta_b(1S)$ with the processes $Y(3S) \rightarrow \pi^+\pi^-\pi^0 h_b$ and decay to ground state $\gamma\eta_b$. The $h_b(1P)$ state is spin-singlet P-wave bound state of $\bar{b}b$ quarks which was observed for the first time by Belle collaboration with significance of 5.5σ [2]. It has been conjectured that this meson often decays into an intermediate two-body states of B mesons, then undergoes final state interactions. This meson ($h_b(1P)$) is used to study of the P-wave spin-spin (or hyperfine) interaction. Therefore, theoretical calculations on the physical parameters of this meson and their comparison with experimental data should give valuable information as regards the nature of hyperfine interaction. However, most of the theoretical studies deal with the non-perturbative QCD calculations. The mass and leptonic decay constant of $h_b(1P)$ mesons have been calculated [3]. These physical parameters help us to calculate the other physical parameters, i.e., the rates of various decay modes and coupling constants.

In this work, we evaluate the strong coupling constant, $g_{h_b B_c^{PS} B_c^V}$ within the framework of three-point QCD sum rules. We consider contributions of both B_c^V and B_c^{PS} mesons as off-shell states. The contributions of the bare loop diagram and the two-gluon condensate diagrams as radiative corrections are evaluated. We assume that h_b is on-shell, that may decay to the intermediate B_c^V and B_c^{PS} mesons. In this regard, the coupling constants help us to describe the intermediate state of two-body decay of meson into B_c^V and B_c^{PS} mesons when one of these mesons is off-shell. The intermediate states decay into the final states with the exchange of virtual mesons. Indeed, without understanding the mechanism of intermediate states, we are not able to analyze the results of ongoing experiments properly.

Here, we use the same technique for the study of the couplings such as $D^*D_s K$, D_s^*DK [4, 5], $D_0D_s K$, $D_{s0}DK$ [6], $D^*D\pi$ [7], D_sD^*K , D_s^*DK [8], $B_{s0}BK$, $B_{s1}B^*K$ [9], $D_s^*DK^*$ [10] and $\eta_b BB^*$ vertex from QCD sum rule [11], B_s^*BK [12], $B_{1s}B^*K$ [13], $B^*B^*\rho$ [13].

The present work is organized as follows: In section II, we introduce the QCD sum rules technique where analytical expressions of the $g_{h_b B_c^V B_c^{PS}}$ strong coupling constant are obtained. Section III is devoted to the numerical analysis and discussion.

II. QCD SUM RULES FOR THE FORM FACTORS

In this section, we present QCD sum rules calculation for the form factor of the $h_b B_c^V B_c^{PS}$ vertex. The three-point correlation function associated with the $h_b B_c^V B_c^{PS}$ vertex is given by

$$\Pi_{\mu\nu}^{B_c^{PS}}(p', q) = i^2 \int d^4x d^4y e^{ip' \cdot x} e^{iq \cdot y} \langle 0 | T(j_\nu^{B_c^V}(x) j_\mu^{B_c^{PS}}(y) j_\mu^{h_b}(0)) | 0 \rangle, \quad (1)$$

where, the B_c^{PS} is off-shell state, and:

$$\Pi_{\mu\nu}^{B_c^V}(p', q) = i^2 \int d^4x d^4y e^{ip' \cdot x} e^{iq \cdot y} \langle 0 | T(j_\nu^{B_c^{PS}}(x) j_\nu^{B_c^V}(y) j_\mu^{h_b}(0)) | 0 \rangle, \quad (2)$$

where the B_c^V is off-shell state, q is transferred momentum, and T is the time ordering operator.

We describe each meson field in terms of the quark field operators as follows:

$$\begin{aligned} j_\nu^{B_c^V}(x) &= \bar{c}(x) \gamma_\nu b(x) \\ j_\mu^{B_c^{PS}}(y) &= \bar{c}(y) \gamma_5 b(y) \\ j_\mu^{h_b}(0) &= \bar{b}(0) \gamma_\mu \gamma_5 b(0) \end{aligned} \quad (3)$$

The above correlation functions need to be calculated in two different ways: on the theoretical side, they are evaluated with the help of the operator-product expansion (OPE), where the short and large-distance effects are separated; on the phenomenological side, they are calculated in terms of hadronic parameters such as masses, leptonic decay constants, and form factors. Finally, we aim to equate structures of the two representations.

Performing the integration over x and y of Eq. (1) we get:

$$\Pi_{\mu\nu}^{B_c^{PS}}(p', q) = \frac{\langle 0 | j_\nu^{B_c^V} | B_c^V(p', \epsilon') \rangle \langle 0 | j_\mu^{B_c^{PS}} | B_c^{PS}(q) \rangle \langle B_c^V(p', \epsilon') | B_c^{PS}(q) | h_b(p, \epsilon) \rangle \langle h_b(p, \epsilon) | j_\mu^{h_b} | 0 \rangle}{(q^2 - m_{B_c^{PS}}^2)(p^2 - m_{h_b}^2)(p'^2 - m_{B_c^V}^2)} + \dots \quad (4)$$

In order to finalize the calculation of the phenomenological side, it is necessary to know the effective Lagrangian for the interaction of the the vertex $h_b B_c^V B_c^{PS}$, which is given as follows:

$$\mathcal{L} = g_{h_b B^V B^{PS}} B^{PS} \{ (\partial_\alpha h^\sigma) (\partial^\alpha B_\sigma^V) - (\partial^\beta h_\alpha) (\partial^\alpha B_\beta^V) \} \quad (5)$$

where h is axial-vector meson field ($h_b(1P)$ field), B^V is the vector meson field and B^{PS} is the pseudoscalar meson field.

The matrix elements of the Eq. (4) can be related to the hardronic parameters as follows:

$$\begin{aligned} \langle 0 | j_\nu^{B_c^V} | B_c^V(p', \epsilon') \rangle &= m_{B_c^V} f_{B_c^V} \epsilon'_\nu \\ \langle 0 | j^{B_c^{PS}} | B_c^{PS}(q) \rangle &= i \frac{m_{B_c^{PS}}^2}{m_b + m_c} f_{B_c^{PS}} \\ \langle B_c^V(p', \epsilon') | B_c^{PS}(q) | h_b(p, \epsilon) \rangle &= i g_{h_b B B}^{B_c^{PS}} [(p.p')(\epsilon.\epsilon'^*) - (p.\epsilon'^*)(p'.\epsilon)] \\ \langle h_b(p, \epsilon) | j_\mu^{h_b} | 0 \rangle &= m_{h_b} f_{h_b} \epsilon_\mu^* \end{aligned} \quad (6)$$

where; $g_{h_b B B}$ is strong coupling constant when B_c^{PS} is off-shell and ϵ and ϵ' are the polarization vectors associated with the h_b and B_c^V respectively. Substituting Eq. (6) in Eq. (4) and using the summation over polarization vectors via,

$$\epsilon_\nu \epsilon_\theta^* = -g_{\nu\theta} + \frac{q_\nu q_\theta}{m_{B_c^{PS}}^2}, \quad (7)$$

$$\epsilon'_j \epsilon_\mu^* = -g_{j\mu} + \frac{p_j p_\mu}{m_{B_c^V}^2}, \quad (8)$$

the phenomenological or physical side for B_c^V off-shell result is found to be:

$$\Pi_{\mu\nu}^{B_c^V}(p', q) = -g_{h_b B B}^{B_c^V}(q^2) \frac{m_{B_c^V} f_{B_c^V} \frac{m_{B_c^{PS}}^2}{m_b + m_c} f_{B_c^{PS}} m_{h_b} f_{h_b}}{(q^2 - m_{B_c^{PS}}^2)(p^2 - m_{h_b}^2)(p'^2 - m_{B_c^V}^2)} (p.p') g_{\mu\nu} + \dots \quad (9)$$

and "..." represents the contribution of the higher states and continuum.

We compare the coefficient of the $(p.p')g_{\mu\nu}$ structure for further calculation from different approaches of the correlation functions.

Also, a similar expression of the physical side of the correlation function for B_c^{PS} off-shell meson is the following:

$$\Pi_{\mu\nu}^{B_c^{PS}}(p', q) = -g_{h_b B B}^{B_c^{PS}}(q^2) \frac{m_{B_c^V} f_{B_c^V} \frac{m_{B_c^{PS}}^2}{m_b + m_c} f_{B_c^{PS}} m_{h_b} f_{h_b}}{(q^2 - m_{B_c^{PS}}^2)(p^2 - m_{h_b}^2)(p'^2 - m_{B_c^V}^2)} (p.p') g_{\mu\nu} + \dots \quad (10)$$

In the following, we calculate the correlation functions on the QCD side using the deep Euclidean space ($p^2 \rightarrow -\infty$ and $p'^2 \rightarrow -\infty$). Each invariant amplitude $\Pi_{\mu\nu}^i(p', q)$ where i stands for B_c^{PS} or B_c^V consists of perturbative (bare loop, see Fig. 1), and non-perturbative parts (the contributions of two-gluon condensate diagrams, see Fig. (2)) as:

$$\Pi_{\mu\nu}^i(p', q) = (\Pi_{per} + \Pi_{nonper})(p.p') g_{\mu\nu} \quad (11)$$

The perturbative contribution and gluon condensate contribution can be defined in terms of double dispersion integral as

$$\Pi_{per} = -\frac{1}{4\pi^2} \int ds' \int ds \frac{\rho(s, s', q^2)}{(s - p^2)(s' - p'^2)} + \text{subtraction terms}, \quad (12)$$

where, $\rho(s, s', q^2)$ is the spectral density. It is aimed to evaluate the spectral density by considering the bare loop diagrams (a) and (b) in Fig. 1 for B_c^V and B_c^{PS} off-shell, respectively. We use the Cutkosky method to calculate these bare loop diagrams and replace the quark propagators of Feynman integrals with the Dirac Delta Function:

$$\frac{1}{q^2 - m^2} \rightarrow (-2\pi i)\delta(q^2 - m^2). \quad (13)$$

Results of spectral density are found to be:

$$\begin{aligned} \rho^{B_c^{PS}}(s, s', q^2) = & \frac{N_c}{\lambda^{3/2}(s, s', q^2)} \{2m_b^2 m_c s - m_c s(2mc^2 + q^2 + s - s') \\ & + 2m_b^3(q^2 + s') - m_b(2m_c^2 + q^2 + s - s')(q^2 + s')\}, \end{aligned} \quad (14)$$

and:

$$\begin{aligned} \rho^{B_c^V}(s, s', q^2) = & \frac{N_c}{\lambda^{3/2}(s, s', q^2)} \{2m_b^2 m_c s - m_c s(2mc^2 + q^2 + s - s') \\ & + 2m_b^3(q^2 + s') - m_b(2m_c^2 + q^2 + s - s')(q^2 + s')\}, \end{aligned} \quad (15)$$

where $\lambda(a, b, c) = a^2 + b^2 + c^2 - 2ac - 2bc - 2ab$ and the color number $N_c = 3$. The physical region in s and s' plane

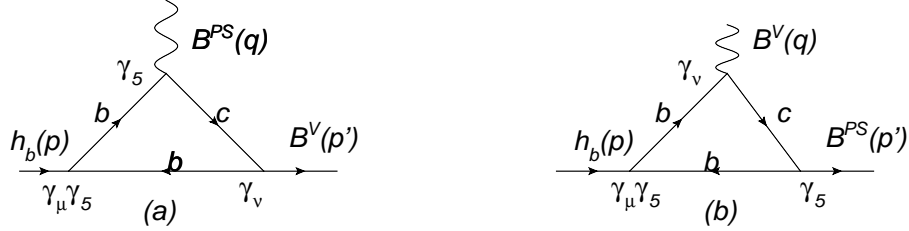

FIG. 1. (a) and (b): Bare loop diagram for the B_c^{PS} and B_c^V off-shell, respectively;

is described by the following inequality:

$$-1 \leq f^i(s, s') = \frac{s(-2m_b^2 + 2m_c^2 + q^2 + s - s')}{\lambda^{1/2}(m_b^2, m_b^2, s)\lambda^{1/2}(s, s, q^2)} \leq 1. \quad (16)$$

where i indicates two states of B_c^{PS} and B_c^V off-shell meson.

The diagrams for the contribution of the gluon condensate in the case B_c^{PS} off-shell are depicted in (a), (b), (c), (d), (e) and (f) in Fig. (2). All diagrams are calculated in the Fock-Schwinger fixed-point gauge[14–16] where we assume $x^\mu A_\mu^a = 0$ for the gluon field A_μ^a . Then, the vacuum gluon field is

$$A_\mu^a(k') = -\frac{i}{2}(2\pi)^4 G_{\rho\mu}^a(0) \frac{\partial}{\partial k'_\rho} \delta^{(4)}(k'), \quad (17)$$

where k' is the gluon momentum.

In this calculation, we need to solve the following two types of integrals:

$$\begin{aligned} I_0[a, b, c] &= \int \frac{d^4 k}{(2\pi)^4} \frac{1}{[k^2 - m_b^2]^a [(p+k)^2 - m_b^2]^b [(p'+k)^2 - m_c^2]^c}, \\ I_\mu[a, b, c] &= \int \frac{d^4 k}{(2\pi)^4} \frac{k_\mu}{[k^2 - m_b^2]^a [(p+k)^2 - m_b^2]^b [(p'+k)^2 - m_c^2]^c}, \end{aligned} \quad (18)$$

where k is the momentum of the spectator quark b . These integrals can be calculated by flipping to Euclidean space-time and using Schwinger representation for the Euclidean propagator

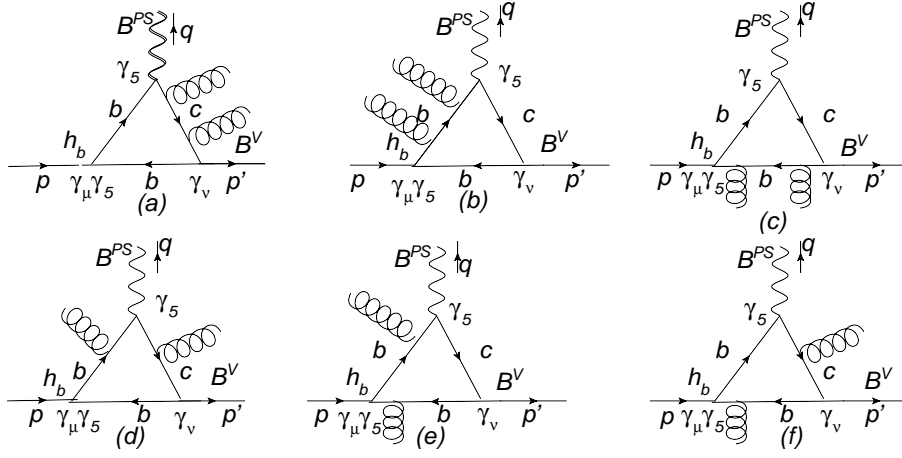

FIG. 2. Two-gluon condensate diagram as a radiative corrections for the B_c^{PS} off-shell;

$$\frac{1}{(k^2 + m^2)^n} = \frac{1}{\Gamma(n)} \int_0^\infty d\alpha \alpha^{n-1} e^{-\alpha(k^2 + m^2)}, \quad (19)$$

the Borel transformation is as follows:

$$B_p(M^2) e^{-\alpha p^2} = \delta\left(\frac{1}{M^2} - \alpha\right). \quad (20)$$

where M is Borel parameter.

We integrate over loop momentum and two parameters that we have used in the exponential representation of propagators [15]. We also apply double Borel transformations over p^2 and p'^2 . The results after the Borel transformations are as follows:

$$\begin{aligned} \hat{I}_0(a, b, c) &= i \frac{(-1)^{a+b+c}}{16\pi^2 \Gamma(a) \Gamma(b) \Gamma(c)} (M_1^2)^{2-a-b} (M_2^2)^{2-a-c} \mathcal{U}_0(a+b+c-4, 1-c-b), \\ \hat{I}_{0\mu}(a, b, c) &= \hat{I}_1(a, b, c) p_\mu + \hat{I}_2(a, b, c) p'_\mu, \end{aligned} \quad (21)$$

where

$$\begin{aligned} \hat{I}_1(a, b, c) &= i \frac{(-1)^{a+b+c+1}}{16\pi^2 \Gamma(a) \Gamma(b) \Gamma(c)} (M_1^2)^{2-a-b} (M_2^2)^{3-a-c} \mathcal{U}_0(a+b+c-5, 1-c-b), \\ \hat{I}_2(a, b, c) &= i \frac{(-1)^{a+b+c+1}}{16\pi^2 \Gamma(a) \Gamma(b) \Gamma(c)} (M_1^2)^{3-a-b} (M_2^2)^{2-a-c} \mathcal{U}_0(a+b+c-5, 1-c-b), \end{aligned} \quad (22)$$

and M_1^2 and M_2^2 are the Borel parameters. The function $\mathcal{U}_0(\alpha, \beta)$ is as follows:

$$\mathcal{U}_0(a, b) = \int_0^\infty dy (y + M_1^2 + M_2^2)^a y^b \exp\left[-\frac{B_{-1}}{y} - B_0 - B_1 y\right],$$

where

$$\begin{aligned} B_{-1} &= \frac{1}{M_1^2 M_2^2} [m_c^2 M_1^4 + m_b^2 M_2^4 + M_2^2 M_1^2 (m_b^2 + m_c^2 - q^2)], \\ B_0 &= \frac{1}{M_1^2 M_2^2} [(m_b^2 + m_c^2) M_1^2 + 2 M_2^2 m_b^2], \\ B_1 &= \frac{m_b^2}{M_1^2 M_2^2}. \end{aligned} \quad (23)$$

The circumflex of \hat{I} in the equations is used for the result of integrals after the double Borel transformation. After lengthy calculations, the following expressions for the two-gluon condensate contributions are obtained:

$$\begin{aligned}\Gamma_{nonper}^{B_c^{PS}} = & 16(6m_b^3(2I_1(1, 4, 1) + 3I_1(4, 1, 1) + I_2(1, 4, 1)) - 6m_b^2m_c(I_1(4, 1, 1) + I_2(1, 4, 1)) \\ & + m_b(6m_c^2(2I_1(1, 1, 4) + I_2(1, 1, 4)) - 2I_1(1, 2, 2) + 6I_1(1, 3, 1) + 6I_1(2, 1, 2) \\ & - 2I_1(2, 2, 1) + 6I_1(3, 1, 1) - I_2(1, 2, 2) + 6I_2(1, 3, 1) + 3I_2(2, 1, 2) - I_2(2, 2, 1)) \\ & + m_c(-6m_c^2I_2(1, 1, 4) - 6I_2(1, 1, 3) + I_2(1, 2, 2) - 3I_2(2, 1, 2) + I_2(2, 2, 1)))\end{aligned}\quad (24)$$

$$\begin{aligned}\Gamma_{nonper}^{B_c^V} = & -16(-m_b(I(2, 1, 2) + I(2, 2, 1) - 12m_c^2I_1(1, 1, 4) - 6I_1(1, 2, 2) - 6I_1(1, 3, 1) \\ & + 2I_1(2, 1, 2) + 2I_1(2, 2, 1) - 6I_1(3, 1, 1) - 6m_c^2I_2(1, 1, 4) - 3I_2(1, 2, 2) - 6I_2(1, 3, 1) + I_2(2, 1, 2) \\ & + I_2(2, 2, 1)) + 6m_b^3(2I_1(1, 4, 1) + 3I_1(4, 1, 1) + I_2(1, 4, 1)) - 6m_b^2m_c(I_1(4, 1, 1) + I_2(1, 4, 1)) \\ & + m_c(-6m_c^2I_2(1, 1, 4) - 6I_2(1, 1, 3) - 3I_2(1, 2, 2) + I_2(2, 1, 2) + I_2(2, 2, 1)))\end{aligned}\quad (25)$$

After applying the Borel transformation to both physical and theoretical sides, we equate the coefficients of the $(p.p')g_{\mu\nu}$ structure from both sides(physical and QCD sides). The results related to the sum rules for the corresponding form factors are found to be:

$$\begin{aligned}g_{h_b B_c^{PS} B_c^V}^i(q^2) = & \frac{2(q^2 - m_i^2)(m_b + m_c)}{f_{h_b} f_{B_c^{PS}} f_{B_c^V} m_{B_c^{PS}}^2 m_{h_b} m_{B_c^V}} e^{\frac{m_{h_b}^2}{M^2}} e^{\frac{m_{(j)}^2}{M'^2}} \left[\frac{1}{4\pi^2} \int_{4m_b^2}^{s_0} ds \int_{(m_b+m_c)^2}^{s'_0} ds' \rho^i(s, s', q^2) \right. \\ & \left. \theta[1 - (f^i(s, s'))^2] e^{\frac{-s}{M^2}} e^{\frac{-s'}{M'^2}} + \Pi_{nonper}^i \right],\end{aligned}\quad (26)$$

where; i and j are either B_c^{PS} or B_c^V , where $(i \neq j)$.

III. NUMERICAL ANALYSIS

In this study, we calculate the form factor with both the $\bar{M}S$ and pole masses. The values given in the Review of Particle Physics are $\bar{m}_c(\bar{m}_c^2) = 1.275 \pm 0.025 \text{ GeV}$ and $\bar{m}_b(\bar{m}_b^2) = 4.18 \pm 0.03 \text{ GeV}$ [17], which correspond to the pole masses $m_c = 1.65 \pm 0.07 \text{ GeV}$ and $m_b = 4.78 \pm 0.06 \text{ GeV}$ [18, 19]. A summary of the other input parameters are given in Table I.

TABLE I: Values of pole masses of quarks and decay constants used in the calculation.

| $m_{B_c^{PS}}$ [17] | $m_{B_c^V}$ [18] | m_{h_b} [17] | $f_{B_c^V}$ [18] | $f_{B_c^{PS}}$ [20] | f_{h_b} [3] |
|---------------------|-------------------|---------------------|-------------------|---------------------|------------------|
| 6.2745 ± 0.0018 | 6.331 ± 0.017 | $9.899.3 \pm 0.001$ | 0.415 ± 0.031 | 0.40 ± 0.025 | 0.094 ± 0.01 |

The sum rules contain auxiliary parameters, namely Borel mass parameters M^2, M'^2 and continuum threshold (s_0 and s'_0). The standard criterion in QCD sum rules is that the physical quantities are independent of the auxiliary parameters. Therefore, we search for the intervals of these parameters so that our results are almost insensitive to their variations. One more condition for the intervals of the Borel mass parameters is the fact that the aforementioned intervals must suppress the higher states, continuum and contributions of the highest-order operators. In other words, the sum rules for the form factors must converge. As a result, we get $25 \text{ GeV}^2 \leq M^2 \leq 30 \text{ GeV}^2$ and $20 \text{ GeV}^2 \leq M'^2 \leq 25 \text{ GeV}^2$ for both B_c^{PS} and B_c^V off-shell associated with the $h_b B_c^{PS} B_c^V$ vertex.

We depict the dependence of strong coupling constants on Borel parameters for B_c^V off-shell in Figs. 3 and 4) These figures indicate the weak dependence of form factor of B_c^V off-shell in terms of the Borel mass parameters in the chosen intervals. We find stable behavior of coupling constant in terms of the Borel mass parameters for the B_c^{PS} off-shell case and we find it unnecessary to show the other figures.

The continuum thresholds s_0 and s'_0 are not arbitrary, but correlated to the energy of the first excited state with the same quantum number as the interpolating current. Thus, we choose the following regions for the continuum thresholds in s_0 and s'_0 channels:

$$(m_{h_b} + 0.4)^2 \leq s_0 \leq (m + 0.6)^2 \quad (27)$$

in s channel for both off-shell cases,

$$(m_{B_c^{PS}} + 0.4)^2 \leq s'_0 \leq (m_{B_c^{PS}} + 0.6)^2 \quad (28)$$

$$(m_{B_c^V} + 0.4)^2 \leq s'_0 \leq (m_{B_c^V} + 0.6)^2 \quad (29)$$

for B_c^{PS} and B_c^V off-shell cases, respectively in s'_0 channel.

As a final remark, we should say that we follow the standard procedure in the QCD sum rules where the continuum thresholds are supposed to be independent of the Borel mass parameters and of q^2 . However, this standard assumption seems not to be accurate, as mentioned in Ref.[21].

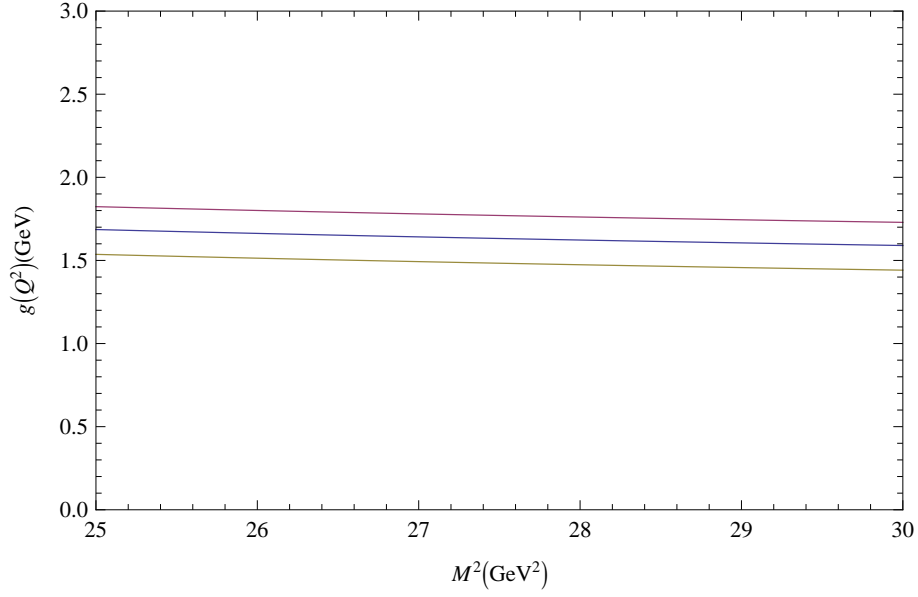

FIG. 3. $g_{h_b B_c^V B_c^{PS}}^{B_c^{PS}}(Q^2 = 5 \text{ GeV}^2)$ as a function of the Borel mass M^2 . The continuum thresholds, $s_0 = (106.08, 108.16, 110.25) \text{ GeV}^2$, $s'_0 = (45.3, 46.66, 48.3) \text{ GeV}^2$ and $M'^2 = 20 \text{ GeV}^2$ are used. The green, blue and purple lines are for minimum central and maximum values of s_0 and s'_0

Our further numerical analysis shows that the dependence of the form factors on q^2 with the definite values of auxiliary parameters fits with the following function:

$$g_{h_b B_c^V B_c^{PS}}^i(Q^2) = A e^{B Q^2} + C \quad (30)$$

where $Q^2 = -q^2$, i stands for B_c^{PS} and B_c^V off-shell cases, and the value of A , B and C are shown in Table II.

By definition, the coupling constant is the value of $g_{h_b B_c^V B_c^{PS}}^i(Q^2)$ at $Q^2 = -m_{meson}^2$ [6], where m_{meson} is the mass of the on-shell mesons.

TABLE II. Value of A , B and C for fit function for B_c^{PS} and B_c^V off-shell cases:

| | B_c^V off-shell | B_c^{PS} off-shell |
|-----|-------------------|----------------------|
| A | 2.30 ± 0.50 | 2.43 ± 0.51 |
| B | 0.035 ± 0.008 | 0.033 ± 0.008 |
| C | -0.31 ± 0.01 | -0.36 ± 0.11 |

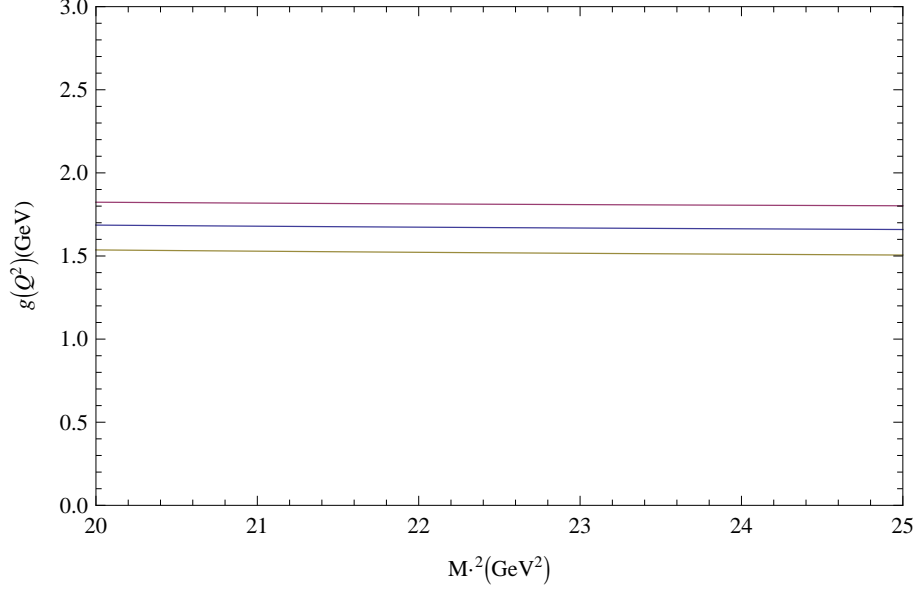

FIG. 4. $g_{h_b B_c^V B_c^{PS}}^{B_c^{PS}}(Q^2 = 5 \text{ GeV}^2)$ as a function of the Borel mass M^2 . The continuum thresholds, $s_0 = (106.08, 108.16, 110.25) \text{ GeV}^2$, $s'_0 = (45.3, 46.66, 48.3) \text{ GeV}^2$ and $M^2 = 25 \text{ GeV}^2$ are used. The green, blue and purple lines are for minimum central and maximum values of s_0 and s'_0

Substituting $Q^2 = -m_{B_c^{PS}}^2$ and $Q^2 = -m_{B_c^V}^2$ in Eq. (30), the $g_{h_b B_c^V B_c^{PS}}^{B_c^{PS}} = 8.80 \pm 2.84 \text{ GeV}^{-1}$ and $g_{h_b B_c^V B_c^{PS}}^{B_c^V} = 9.34 \pm 3.12 \text{ GeV}^{-1}$ are obtained for B_c^{PS} and B_c^V off-shell cases, respectively. The average value of the $g_{h_b B_c^V B_c^{PS}}$ strong coupling constant is found to be

$$g_{h_b B_c^V B_c^{PS}} = (9.07 \pm 2.93) \text{ GeV}^{-1} \quad (31)$$

Note that roughly 80% of the errors in our numerical calculation arise from the variation continuum thresholds in intervals shown in Eqs. (27,28) and 29, and remaining 20% occur as a result of the quark masses when one proceeds from the \overline{MS} to the pole-scheme mass parameters, the input parameters.

In conclusion, we calculate the strong coupling constant $g_{h_b B_c^V B_c^{PS}}$ using the three-point QCD sum rules. Our results show that the average value of the strong coupling constant is $g_{h_b B_c^V B_c^{PS}} = (9.93 \pm 2.7) \text{ GeV}^{-1}$. Furthermore, the errors in our numerical calculations depend on continuum threshold and variation of the quark masses in different mass schemes.
